# 12. Assembly Language, Examples (Chapter 7) October 10, 2018

- Assembly Language
  - · Opcodes, operands
  - · Labels, comments
  - Assembler directives
- Example: counting 1s and 0s
- Assembly process
  - · First pass, symbol table
  - · Second pass, machine code
- Example: counting characters in a file

# **An Assembly Language Program**

```
Program to multiply a number by the constant 6
         ORIG
               x3050
       LD
               R1, SIX-
R2, NUMBER
       AND
               R3, R3, #0
                                Clear R3.
                                           It will
                               contain the product.
  The inner loop
ÁGAIN
        ADD
               R3, R3, R2
R1, R1, #-1
AGAIN
                                R1 keeps track of
        BRp
                               the iteration.
        HALT
       BLKW 1
NUMBER
SIX
        . END
       · "KEYWORDS"
```

## **Human-Readable Machine Language**

Computers like ones and zeros...

0001110010000110

Humans like symbols...

ADD R6, R2, R6 ; increment index reg.

# Assembler is a program that turns symbols into machine instructions.

- · ISA-specific:
  - close correspondence between symbols and instruction set
  - > mnemonics for opcodes
  - > labels for memory locations
- additional operations for allocating storage and initializing data

# **LC-3 Assembly Language Syntax**

Each line of a program is one of the following:

- an instruction
- an assember directive (or pseudo-op)
- a comment

Whitespace (between symbols) and case are ignored. Comments (beginning with ";") are also ignored.

An instruction has the following format:

# **Opcodes and Operands**

#### **Opcodes**

- · reserved symbols that correspond to LC-3 instructions
- listed in Appendix A

```
>ex: ADD, AND, LD, LDR, ...
```

#### **Operands**

- · registers -- specified by Rn, where n is the register number
- numbers -- indicated by # (decimal) or x (hex) or b (binary)
- · label -- symbolic name of memory location
- · separated by comma
- number, order, and type correspond to instruction format

>ex:

ADD R1,R1,R3

ADD R1,R1,#3

LD R6,NUMBER

BRZ LOOP

#### **Assembler Directives**

#### **Pseudo-operations**

- · do not refer to operations executed by program
- · used by assembler
- look like instruction, but "opcode" starts with dot

Opcode	Operand	Meaning
.ORIG	address	starting address of program
.END		end of program
.BLKW	n -	allocate n words of storage
.FILL	n	allocate one word, initialize with value n
.STRINGZ	n-character string	allocate n+1 locations, initialize w/characters and null terminator

#### **Labels and Comments**

#### Labe

- · placed at the beginning of the line
- assigns a symbolic name to the address corresponding to line
   ex:

#### Comment

- · anything after a semicolon is a comment
- · ignored by assembler
- · used by humans to document/understand programs
- tips for useful comments:
  - > avoid restating the obvious, as "decrement R1"
  - > provide additional insight, as in "accumulate product in R6"
  - > use comments to separate pieces of program

# **Trap Codes**

LC-3 assembler provides "pseudo-instructions" for each trap code, so you don't have to remember them.

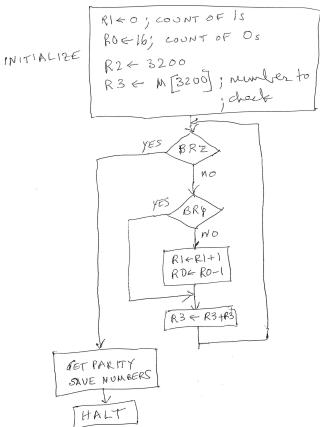

Code	Equivalent	Description
HALT	TRAP x25	Halt execution and print message to console.
IN	TRAP x23	Print prompt on console, read (and echo) one character from keybd. Character stored in R0[7:0].
OUT	TRAP x21	Write one character (in R0[7:0]) to console.
GETC	TRAP x20	Read one character from keyboard. Character stored in R0[7:0].
PUTS	TRAP x22	Write null-terminated string to console. Address of string is in R0.

# **Style Guidelines**

Use the following style guidelines to improve the readability and understandability of your programs:

- 1. Provide a program header, with author's name, date, etc., and purpose of program.
- Start labels, opcode, operands, and comments in same column for each line. (Unless entire line is a comment.)
- 3. Use comments to explain what each register does.
- 4. Give explanatory comment for most instructions.
- 5. Use meaningful symbolic names.
  - · Mixed upper and lower case for readability.
  - ASCIItoBinary, InputRoutine, SaveR1
- 6. Provide comments between program sections.
- 7. Each line must fit on the page -- no wraparound or truncations.
  - · Long statements split in aesthetically pleasing manner.

# Counting the number of ones (and zeroes) in assembly language

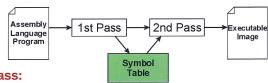

# Assembly language program to count 1s, 0s and find even parity bit for a word

```
.ORIG
              x3000
              R1, R1, #0
       AND
                             count of 1s (start with 0)
              RO, SIXTEEN
                            ; start with a count of 16 for 0s
              R2, NUMBER
                             address of number to test
       LD
                             get number to be tested
       LDR
              R3, R2, #0
L00P
              DONE
                             zero, we are done counting
       Brz
                            ; positive, no 1 in bit 15
       BRp
              NO
                            ; negative, increment count of 1s
              R1, R1, #1
       ADD
                                        decrement count of 0s
              R0, R0, #-1
       ADD
                             shifting number left
NO
       ADD
              R3, R3, R3
             1.00P
       BRnzp
             R1, R2, #1
DONE
                           ; save count of 1s in x3201
      STR
                           ; save count of 0s in x3202
       STR
             R0, R2, #2
                             parity is the LSB of the count
       AND
             R1, R1, #1
       STR
             R1, R2, #3
                             save parity in x3203
      HALT
SIXTEEN .FILL x10
NUMBER .FILL
              x3200
```

.END

# **Assembly Process**

Convert assembly language file (.asm) into an executable file (.obj) for the LC-3 simulator.

# First Pass:

- · scan program file
- find all labels and calculate the corresponding addresses; this is called the <u>symbol table</u>

#### **Second Pass:**

 convert instructions to machine language, using information from symbol table

# **First Pass: Constructing the Symbol Table**

- 1. Find the .ORIG statement,
  - which tells us the address of the first instruction.
  - Initialize Location counter (LC), which keeps track of the current instruction.
- 2. For each non-empty line in the program:
  - a) If line contains a label, add label and LC to symbol table.
  - b) Increment LC.
    - NOTE: If statement is .BLKW or .STRINGZ, increment LC by the number of words allocated.
- 3. Stop when . END statement is reached.

NOTE: A line that contains only a comment is considered an empty line.

# **Second Pass: Generating Machine Language**

For each executable assembly language statement, generate the corresponding machine language instruction.

If operand is a label, look up the address from the symbol table.

#### Potential problems:

· Improper number or type of arguments

>ex: NOT R1,#7

ADD R1, R2

ADD R3, R3, NUMBER

· Immediate argument too large

≽ex: ADD R1,R2,#1023

· Address (associated with label) more than 256 from instruction > can't use PC-relative addressing mode

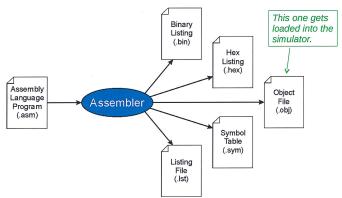

#### **Practice**

Construct the symbol table for the program to multiply a number by 6

Symbol	Address
(.ORIG) (=LC)	x 3050
A GAIN	X-3053
NUMBER	X 3057
S17	X3058

#### LC-3 Assembler

Using "assemble" (Unix) or LC3Edit (Windows), generates several different output files.

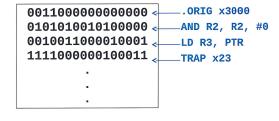

## **Object File Format**

LC-3 object file contains

- Starting address (location where program must be loaded), followed by...
- · Machine instructions

# **Example**

· Beginning of "count character" object file looks like this:

# **Multiple Object Files**

An object file is not necessarily a complete program.

- system-provided library routines
- · code blocks written by multiple developers

For LC-3 simulator, can load multiple object files into memory, then start executing at a desired address.

- system routines, such as keyboard input, are loaded automatically
  - > loaded into "system memory," below x3000
  - > user code should be loaded between x3000 and xFDFF
- · each object file includes a starting address
- · be careful not to load overlapping object files

# **Linking and Loading**

**Loading** is the process of copying an executable image into memory.

- more sophisticated loaders are able to <u>relocate</u> images to fit into available memory
- · must readjust branch targets, load/store addresses

**Linking** is the process of resolving symbols between independent object files.

- suppose we define a symbol in one module, and want to use it in another
- some notation, such as .EXTERNAL, is used to tell assembler that a symbol is defined in another module
- linker will search symbol tables of other modules to resolve symbols and complete code generation before loading

## **Another Example**

#### Count the occurrences of a character in a file

- Program begins at location x3000
- Read character from keyboard
- · Load each character from a "file"
  - > File is a sequence of memory locations
  - Starting address of file is stored in the memory location immediately after the program
- If file character equals input character, increment counter
- End of file is indicated by a special ASCII value: EOT (x04)
- At the end, print the number of characters and halt (assume there will be less than 10 occurrences of the character)

A special character used to indicate the end of a sequence is often called a sentinel.

• Useful when you don't know ahead of time how many times to execute a loop.
